

HACKCANTON SEASON 3 · RWA & BUSINESS WORKFLOWS

Mobilis

Collateral that moves in one atomic transaction, with every rule enforced by the Canton ledger.

github.com/angelraph/mobilis · mobilis-angelraphs-projects.vercel.app

THE PROBLEM

Every collateral move is checked four times, by hand, by every party

1

Eligible?

Is this asset type allowed under the agreement?

2

Worth?

What is it worth after the agreed haircut?

3

Covered?

Is the exposure still covered after the move?

4

Concentrated?

Is one asset type now too much of the book?

Each party checks on its own copy, over spreadsheets and email. Then they reconcile, and breaches are found after settlement instead of prevented before it.

WHAT IT COSTS

€1.6–8B

a year, industry-wide, in manual collateral and corporate-action processing

46%

of corporate-action data is still handled manually

Putting an asset on a ledger is largely solved. The money is lost in the operational layer: margin calls, substitutions, reconciliation.

Sources: industry estimates; SIX Group.

WHY NOW, WHY CANTON

Securities finance is already moving onto Canton

Broadridge DLR

Distributed Ledger Repo runs on Canton infrastructure

DTCC

Moving tokenised US Treasuries toward production

HQLAx

Collateral-mobility specialist, backed by Broadridge and Digital Asset

Canton Industry Working Group

Working on cross-border collateral mobility this year

Collateral is multi-party and confidential. Canton's atomic settlement and sub-transaction privacy fit it. A public chain or a single shared database doesn't.

THE SOLUTION

The rulebook lives on the ledger

The question	What the Canton ledger does
Eligible?	Rejects ineligible asset types before a move can be agreed
Worth?	Values each lot at the custodian's price mark and the agreed haircut, ignoring what the caller sends
Covered?	Refuses any return or swap that would leave the book short of the margin requirement
Concentrated?	Enforces a cap on each asset type's share of the book
Margin call met?	Can only be marked fulfilled when coverage is really there
Book moved?	Settlement re-checks every rule against the book as it is then
Prices moved?	Custodian marks re-value the whole book; a shortfall blocks releases until a top-up

PRIVACY BY CONSTRUCTION

One transaction, four different views

Pledgor

Its agreement, the live book, every call it's party to

Secured party

The same agreement and book, as the counterparty

Custodian

Everything operational: it settles every move

Regulator

Only the audit report: coverage, positions, breaches

The regulator's node holds no agreement, no schedule and no call. No UI is hiding them: they were never shared with it.

COLLATERAL OPTIMISER

AI that works inside hard rules

"I need my Treasuries back for a repo." The optimiser finds the cheapest swap the agreement allows, and shows why the tempting ones are illegal.

UST out → 925,000 cash in	Valid · coverage 100%
UST out → corporate bonds in	Ruled out · over the 60% limit
UST out → high-yield bonds in	Ruled out · not eligible

The AI only chooses among rule-checked moves, and the ledger checks its choice again at Agree and Settle.

THE DEMO

One margin cycle, live on a Canton ledger

1. Pledgor posts a Treasury bill. The ledger values it at 980,000 after the haircut
2. Margin call for 1,400,000: coverage drops to 70%, and "fulfilled" is refused
3. A corporate bond tops it up. Now the margin call can be fulfilled
4. The optimiser swaps the Treasury for cash in one atomic transaction
5. A swap that would leave the book short is refused at Agree
6. Prices fall: the book re-values, goes short, and the one-click top-up fixes it
7. The regulator sees the report, and nothing else

PROOF

Built, tested and measured

20

Daml tests passing, plus 16 rules checked on ledger and browser

~2s

ledger time for a full margin cycle, 3 runs on a local sandbox

0

raw contracts visible to the regulator

5–8

customer interviews planned with collateral ops teams

Next: a timed manual baseline with a real ops team, and a design-partner pilot on DevNet.

WHO PAYS

Custodians and triparty agents own the cost we remove

The buyer

Heads of collateral operations at mid-size custodians and triparty agents. They settle the moves, reconcile the books and produce the reports.

The model

A platform fee per custodian plus a fee per active agreement (a hypothesis we are validating in interviews), plus Canton Featured App rewards as activity grows.

Users in the workflow: treasury desks (pledgor), lenders (secured party), and regulators and auditors. Not retail, not DeFi traders.

GO TO MARKET

One agreement first, then the whole book

Months 0–3

Design partner

One custodian already on Canton and one of its pledgor clients. One agreement on DevNet, measured against today's process.

Months 3–9

Paid pilot

A pricing feed, the custodian's own participant node, real authentication, one live relationship.

Months 9+

Expand

More agreements per custodian, then netting and portfolio-level optimisation.

Channels: the Canton Industry Working Group, the AppsFactory partner network and Accelerator, and direct outreach to collateral operations leaders.

THE ASK

An introduction to one custodian on Canton, and Accelerator support to run the pilot

Mobilis: every collateral rule enforced by the ledger, every party seeing only its own slice.
